a study of rotor blade aeroelastic stability was carried out using an analytic model of a two dimensional airfoil undergoing dynamic stall and an elastomechanical representation including flapping flapwise bending and torsional degrees of freedom results for a hovering rotor demonstrated that the models used are capable of reproducing both classical and stall flutter the minimum rotor speed for the occurrence of stall flutter in hover was found to be determined from coupling between torsion and flapping instabilities analogous to both classical and stall flutter were found to occur in forward flight however the large stall related torsional oscillations which commonly limit aircraft forward speed appear to be the response to rapid changes in aerodynamic moment which accompany stall and unstall rather than the result of an aeroelastic instability the severity of stall related instabilities and response was found to depend to some extent on linear stability increasing linear stability lessens the susceptibility to stall flutter and reduced the magnitude of the torsional response to stall and unstall
